## Workshop 15 - Simple Nomenclature of Inorganic Compounds

I. Ionic Compounds (Compounds composed of a metal and a nonmetal or a metal and a polyatomic ion.)
A. Monatomic cations (positive ions formed from one atom) from Groups IA, IIA, IIIA and hydrogen take the name of the element from which they were derived.

| $\mathrm{H}^{+}$ | hydrogen | $\mathrm{K}^{+}$ | potassium |
| :--- | :--- | :--- | :--- |
| $\mathrm{Mg}^{+2}$ | magnesium | $\mathrm{Al}^{+3}$ | aluminum |

B. When a metal forms more than one ion (if it has variable ionic charge), it is necessary to distinguish between the possible ions. We will use the Stock method which gives the charge of the ion as a Roman number in parentheses immediately after the name of the metal. This will occur with most of the transition metals and the metals of groups IVA and VA.

| $\mathrm{Fe}^{+2}$ | iron(II) | $\mathrm{Ni}^{+}$ | $\operatorname{nickel(I)}$ | $\mathrm{Pb}^{+2}$ | lead(II) |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{Fe}^{+3}$ | iron(III) | $\mathrm{Ni}^{+2}$ | $\operatorname{nickel(II)}$ | $\mathrm{~Pb}^{+4}$ | lead(IV) |

C. Monatomic anions (negative ions formed from one atom) are named by adding the suffix -ide to the stem of the name of the nonmetal from which they are derived. These names should be memorized.

| $\mathrm{F}^{-}$ | fluoride | $\mathrm{O}^{-}$ | oxide | $\mathrm{N}^{-3}$ | nitride |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{Cl}^{-}$ | chloride | $\mathrm{S}^{-2}$ | sulfide | $\mathrm{H}^{-}$ | hydride |
| $\mathrm{Br}^{-}$ | bromide | $\mathrm{Se}^{-2}$ | selenide | $\mathrm{I}^{-}$ | iodide |

D. The names and formulas of these polyatomic ions must be memorized. The charge is an essential part of the formula.

| $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{-}$ | acetate | $\mathrm{ClO}^{-}$ | hypochlorite |
| :---: | :---: | :---: | :---: |
| $\mathrm{CO}_{3}{ }^{-2}$ | carbonate | $\mathrm{ClO}_{2}{ }^{-}$ | chlorite |
| $\mathrm{HCO}_{3}{ }^{-}$ | bicarbonate (hydrogen carbonate) | $\mathrm{ClO}_{3}{ }^{-}$ | chlorate |
| $\mathrm{OH}^{-}$ | hydroxide | $\mathrm{ClO}_{4}{ }^{-}$ | perchlorate |
| $\mathrm{NO}_{3}{ }^{-}$ | nitrate | $\mathrm{MnO}_{4}^{-}$ | permanganate |
| $\mathrm{NO}_{2}{ }^{-}$ | nitrite | $\mathrm{SO}_{4}{ }^{-2}$ | sulfate |
| $\mathrm{CrO}_{4}{ }^{-2}$ | chromate | $\mathrm{SO}_{3}{ }^{-2}$ | sulfite |
| $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{-2}$ | dichromate | $\mathrm{HSO}_{3}{ }^{-}$ | bisulfite (hydrogen sulfite) |
| $\mathrm{PO}_{4}{ }^{-3}$ | phosphate | $\mathrm{HSO}_{4}{ }^{-}$ | bisulfate (hydrogen sulfate) |
| $\mathrm{HPO}_{4}{ }^{-2}$ | hydrogen phosphate | $\mathrm{O}_{2}{ }^{-2}$ | peroxide |
| $\mathrm{NH}_{4}^{+}$ | ammonium | $\mathrm{CN}^{-}$ | cyanide |

$\qquad$
E. An ionic compound is a combination of one or more cations, and one or more anions. To name the compound, name the cation, then name the anion.

| $\mathrm{K}_{2} \mathrm{~S}$ | potassium sulfide | $\mathrm{NH}_{4} \mathrm{Cl}$ | ammonium chloride |
| :--- | :--- | :--- | :--- |
| $\mathrm{AlCl}_{3}$ | aluminum chloride | $\mathrm{NH}_{4} \mathrm{NO}_{3}$ | ammonium nitrate |

F. If the cation is a metal with variable ionic charge, you must determine the charge on the metal so that you know what number to put in the parentheses. To do this, look at the anion(s). The charge on the anion(s) multiplied by the number of anions gives the total negative charge. Since the number of positive charges and negative charges in a compound must equal, the total positive charge must be the absolute value of the total negative charge. The total positive charge should be divided by the number of metal ions in the formula to give the charge on an individual ion. This is the number which goes in the parentheses.

| CuBr | copper(I) bromide | $\mathrm{Pb}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{4}$ | lead(IV) acetate |
| :--- | :--- | :--- | :--- |
| $\mathrm{CuBr}_{2}$ | copper(II) bromide | $\mathrm{PbSO}_{4}$ | lead(II) sulfate |
| CuS | copper(II) sulfide | $\mathrm{NiCl}_{2}$ | nickel(II) chloride |
| $\mathrm{Fe}(\mathrm{OH})_{3}$ | iron(III) hydroxide | $\mathrm{Cu}_{2} \mathrm{SO}_{3}$ | copper(I) sulfite |

G. The formula of an ionic compound must contain equal numbers of positive charges and negative charges. When you are given a name and you need to write a formula, you may need to use several cations and/or anions for the number of charges to be equal. Often, you can use the charge on the cation as the number of anions and the absolute value of the charge on the anion as the number of cations. However, sometimes when you try to do this you will get a formula where the number of cations and the number of anions have a common factor. In this case you must divide both numbers by that common factor to give you the correct empirical formula.

| aluminum iodide | $\mathrm{AlI}_{3}$ | sodium sulfide | $\mathrm{Na}_{2} \mathrm{~S}$ |
| :--- | :--- | :--- | :--- |
| tin(IV) chloride | $\mathrm{SnCl}_{4}$ | iron(III) oxide | $\mathrm{Fe}_{2} \mathrm{O}_{3}$ |
| chromium(VI) oxide | $\mathrm{CrO}_{3}$ | magnesium oxide | MgO |

## II. Binary Compounds of Two Nonmetals (Covalent Compounds)

A. A compound composed of two nonmetals is a covalent compound. The compound's name is written by taking the less electronegative element first, writing the name of that element, then taking the more electronegative element and adding the -ide suffix to the stem of the name of the element. If more than one atom of an element is in the formula, prefixes are used to indicate the numbers. These prefixes are:

| 2 | di- | 5 | penta- | 8 | octa- |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 3 | tri- | 6 | hexa- | 9 | nona- |
| 4 | tetra- | 7 | hepta- | 10 | deca- |

The prefix for one is mono-, but it no longer has to be used.

| $\mathrm{P}_{4} \mathrm{O}_{10}$ | tetraphosphorus decoxide | $\mathrm{NF}_{3}$ | nitrogen trifluoride |
| :--- | :--- | :--- | :--- |
| $\mathrm{CCl}_{4}$ | carbon tetrachloride | $\mathrm{SiO}_{2}$ | silicon dioxide |
| $\mathrm{CS}_{2}$ | carbon disulfide | NO | nitrogen oxide |
| $\mathrm{Cl}_{2} \mathrm{O}$ | dichlorine oxide | $\mathrm{N}_{2} \mathrm{O}_{3}$ | dinitrogen trioxide |

$\qquad$
B. There are several binary compounds that have common names.

$$
\mathrm{H}_{2} \mathrm{O} \quad \text { water } \quad \mathrm{NH}_{3} \quad \text { ammonia } \quad \mathrm{CH}_{4} \quad \text { methane* }
$$

*For organic hydrocarbons (carbon and hydrogen), a different method is employed for naming.
III. Acids
A. Acids are compounds that contain hydrogen and which, under certain conditions, ionize to form hydrogen ions and a negative nonmetal ion or a negative polyatomic ion. You can always recognize the formula of an acid because in acids, but not in other compounds, the H is written first. (Water is a very weak acid.)
B. Binary acids: Binary acids contain hydrogen and one other element. They are formed from hydrogen ions and a monatomic nonmetal ion. They are given two different names depending on whether or not they are dissolved in water. If they are dissolved in water their names are formed by taking the name of the anion, dropping the -ide suffix, and then adding both the hydro- prefix and the -ic acid suffix. If binary acids are not dissolved in water, they are named as ionic compounds.

| $\mathrm{HCl}(\mathrm{aq})$ | hydrochloric acid | $\mathrm{HCl}(\mathrm{g})$ | hydrogen chloride |
| :--- | :--- | :--- | :--- |
| $\mathrm{HF}(\mathrm{aq})$ | hydrofluoric acid | $\mathrm{HF}(\mathrm{g})$ | hydrogen fluoride |
| $\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq})$ | hydrosulfuric acid | $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$ | hydrogen sulfide |

C. Oxyacids: Oxyacids are acids that contain oxygen in addition to hydrogen and another element. They can be formed by combining hydrogen ions and polyatomic anions. For Chem 12, you only need to worry about the acids of polyatomic ions that end in -ate. For these acids, the acid is named by taking the name of the polyatomic ion and changing the -ate ending to -ic acid. Note that the "hydro-" prefix is only used for binary acids, not for oxyacids.

The names of oxyacids are the same whether or not they are dissolved in water.

| $\mathrm{HNO}_{3}$ | nitric acid | $\mathrm{HC}_{2} \mathrm{H}_{3} \mathrm{O}_{2}$ | acetic acid |
| :--- | :--- | :--- | :--- |
| $\mathrm{HClO}_{3}$ | chloric acid | $\mathrm{H}_{2} \mathrm{CO}_{3}$ | carbonic acid |

There are several acids whose names are not quite what you would expect. Memorize these names.
$\mathrm{H}_{2} \mathrm{SO}_{4}$ sulfuric acid (not sulfic acid)
$\mathrm{H}_{3} \mathrm{PO}_{4} \quad$ phosphoric acid (not phosphic acid)
D. To write the formula of an acid when given the acid's name, determine the name of the anion that corresponds to the acid by using the rules in section B and C in reverse. For each negative charge on the formula of the anion, add one $\mathrm{H}^{+}$in order to give a neutral formula.
$\begin{array}{ll}\text { hydroselenic acid } & \mathrm{H}_{2} \mathrm{Se}(\mathrm{aq}) \\ \text { perchloric acid } & \mathrm{HClO}_{4}\end{array}$
